

GCE A LEVEL MARKING SCHEME

PREDICTED PAPER – MODERATE

A LEVEL

ECONOMICS – COMPONENT 2

A520U20-1

About this marking scheme

The purpose of this marking scheme is to provide teachers, learners and other interested parties with an understanding of the assessment criteria used to assess this specific assessment.

This predicted (Moderate) marking scheme mirrors the structure, mark allocations and assessment objective weightings of the 2024 WJEC/Eduqas A Level Economics Component 2 paper. It is pitched at a moderate level of difficulty so as to support learners preparing for the full range of Component 2 questions. It is not an official WJEC document.

GENERAL MARKING GUIDANCE

Positive Marking

It should be remembered that learners are writing under examination conditions and credit should be given for what the learner writes, rather than adopting the approach of penalising him/her for any omissions. It should be possible for a very good response to achieve full marks and a very poor one to achieve zero marks.

For each question there is a list of indicative content which suggests the range of economic concepts, theory, issues and arguments which might be included in learners' answers. This is not intended to be exhaustive and learners do not have to include all the indicative content to reach the highest level of the mark scheme.

The level-based mark schemes sub-divide the total mark to allocate to individual assessment objectives. Learners' responses to questions are assessed against the relevant individual assessment objectives and they may achieve different bands within a single question.

GCE A LEVEL ECONOMICS – COMPONENT 2
PREDICTED (MODERATE) MARK SCHEME

Question 1

1	1	Using the data, explain why house prices have risen faster than earnings in the UK since 2000 (Figure 1).		[5]
Band	AO1	AO2	AO3	
2	1 mark Knowledge Clear knowledge of the determinants of house prices (demand/supply) is demonstrated.	2 marks Good application Strong use of Figures 1 and/or 2 to support the argument.	2 marks Good analysis Developed chain of reasoning explaining why prices have outpaced earnings.	
1	1 mark Limited knowledge Some awareness of price determination is shown.	1 mark Limited application Use of the data is limited with few direct references.	1 mark Limited analysis Chain of reasoning is unconvincing or lacking in clarity.	
0	0 marks No knowledge or understanding shown.	0 marks No valid application.	0 marks No valid analysis.	

Indicative content

AO1

House prices are set by the interaction of demand and supply. Shifts in either change the equilibrium price. Persistent outward shifts in demand combined with an inelastic supply produce a rising price trend.

AO2

Figure 1 shows that the UK house-price-to-earnings ratio has roughly doubled from around 4.2 in 2000 to around 8.3 in 2023, indicating that prices have grown almost twice as fast as earnings.

Figure 2 shows that housing completions have consistently fallen short of the 300,000 target – confirming that supply has been slow to respond to demand.

AO3

Demand has risen faster than supply. A growing population, smaller household sizes, migration and rising life expectancy have all increased the number of households seeking homes.

Historically low interest rates between 2009 and 2022 made mortgage borrowing cheaper, supporting higher house prices. Much of the price-to-earnings rise occurred during this cheap-credit era.

Government demand-side schemes (Help to Buy, Stamp Duty relief) further supported demand.

Supply is highly inelastic: planning restrictions, limited land release, skills shortages in construction and the dominance of a few volume house-builders have prevented supply from responding.

Real wages stagnated between 2008 and 2015, so earnings did not keep pace with house prices even when prices paused.

Allow any other valid points.

1	2	Using the data, explain why the UK Government might want to increase the supply of housing in the UK.	[5]
Band	AO2	AO3	
		3 marks Excellent analysis Well-developed chain of reasoning covering multiple reasons why the Government wants to expand supply.	
2	2 marks Good application Strong use of Figures 1, 2 and/or 3 to support the argument.	2 marks Good analysis Developed chain of reasoning explaining why higher supply is desirable.	
1	1 mark Limited application Use of the data is limited with few direct references.	1 mark Limited analysis A chain of reasoning exists, but points are under-developed.	
0	0 marks No valid application.	0 marks No valid analysis.	

Indicative content

AO2

Figure 1 shows a historically high price-to-earnings ratio of over 8, well above long-run norms.

Figure 2 shows completions persistently below the 300,000 target – a supply gap of 60-100,000 homes per year.

Figure 3 shows ownership rates among 25-34 year olds have almost halved since 1991.

AO3

Higher supply would place downward pressure on prices and bring affordability closer to historical norms.

Increasing supply supports home ownership among younger households, addressing inter-generational inequality (Figure 3).

A larger housing stock supports labour mobility: workers can move to take higher-productivity jobs, supporting UK productivity and output.

The construction of new homes generates employment, tax revenue and positive multiplier effects through the supply chain.

Meeting housing demand reduces political pressure on the Government and reduces dependence on expensive private-rental accommodation.

Higher supply could reduce reliance on housing benefit (which costs the Exchequer around £20 billion a year) by lowering rents.

Allow any other valid points.

1	3	How effective is the UK Government's housing strategy (Figure 8) likely to be in improving housing affordability?		[10]
Band	AO2 (3 marks)		AO3 (3 marks)	AO4 (4 marks)
3	3 marks Excellent application Data is well used on both sides of the argument, linking Figure 8 to outcomes in Figures 1, 2 and 7.		3 marks Excellent analysis Well-developed chains of reasoning explaining clearly how the policies would improve affordability.	3-4 marks Excellent evaluation Well-developed chains of reasoning explaining why the policies may be ineffective. Top-band answers give a well-reasoned overall judgement.
2	2 marks Good application Data is well used on one side of the argument.		2 marks Good analysis Developed chains showing how the policies would raise supply or reduce prices.	2 marks Good evaluation Developed counter-arguments about the policies' weaknesses.
1	1 mark Limited application Use of the data is less effective.		1 mark Limited analysis Chains of reasoning are under-developed.	1 mark Limited evaluation Counter-arguments present but under-developed.
0	0 marks No valid application.		0 marks No valid analysis.	0 marks No valid evaluation.

Indicative content

Supply-side reforms (AO3)

Planning reform should in principle allow supply to respond more quickly to price signals, increasing completions and ultimately reducing prices. Completions are well below the 300,000 target (Figure 2).

The £11.5 billion Affordable Homes Programme directly funds genuinely affordable homes, the tenure most needed by lower-income households.

Demand-side support (AO3)

Stamp Duty relief and the Mortgage Guarantee Scheme help first-time buyers reach the bottom of the ladder, supporting ownership among the 25-34 age group (Figure 3).

Regional rebalancing (Freeports, Investment Zones) could spread demand more evenly, easing pressure on London and the South East (Figures 6, 7).

Weaknesses (AO4)

Planning reform has been attempted repeatedly and runs into strong local opposition. Its effects on completions typically take years to materialise.

Demand-side measures risk raising prices because supply is inelastic: subsidising buyers without supply reform tends to inflate prices (Figure 1).

Renters' reforms may reduce landlord profitability; some exit the market, reducing rental supply and raising rents, worsening affordability.

£11.5 billion over five years is modest relative to total UK housing investment; it will not reverse decades of decline in social housing.

The rise in mortgage rates (Figure 5) dominates many of these measures for buyers in the short run – monthly payments on a £250,000 mortgage have roughly doubled since 2021.

Regional rebalancing depends on where demand follows investment; employment typically remains concentrated in the South, limiting the effect.

Overall: the strategy addresses multiple dimensions but under-scales its supply-side response and risks inflating demand. Affordability gains are likely to be slow and uneven. Allow any other valid points.

1	4	Using the data, discuss the extent to which the rise in mortgage rates since 2022 (Figure 5) will affect the UK housing market.		[10]
Band	AO2 (3 marks)	AO3 (3 marks)	AO4 (4 marks)	
3	3 marks Excellent application Figure 5 used in detail alongside other figures on both sides of the argument.	3 marks Excellent analysis Well-developed chains of reasoning on the mortgage-rate transmission to the housing market.	3-4 marks Excellent evaluation Well-developed counter-arguments and a well-reasoned overall judgement.	
2	2 marks Good application Figure 5 well used on one side of the argument.	2 marks Good analysis Developed chains of reasoning.	2 marks Good evaluation Developed counter-arguments.	
1	1 mark Limited application Use of Figure 5 is superficial.	1 mark Limited analysis Chains of reasoning are under-developed.	1 mark Limited evaluation Counter-arguments present but under-developed.	
0	0 marks No valid application.	0 marks No valid analysis.	0 marks No valid evaluation.	

Indicative content

AO2

Figure 5 shows mortgage rates rising from around 1.8% in 2021 to around 5.1% in 2023 – the sharpest rise in a generation. Figure 1 shows the price-to-earnings ratio moderating from around 9.1 in 2022 to around 8.3 in 2023, consistent with some cooling.

Effects on demand (AO3)

Higher mortgage rates increase the monthly cost of servicing a loan. On a £250,000 mortgage, a rise from 2% to 5% raises repayments by roughly £400 per month, pricing many buyers out.

Reduced affordability shifts demand leftwards. Prices should fall, bringing the price-to-earnings ratio closer to historic norms (Figure 1).

Demand from buy-to-let investors also falls as rental yields compress against rising finance costs.

Transaction volumes fall as households delay moving – the market becomes less liquid.

Counter-arguments (AO4)

Most UK mortgages are 2- or 5-year fixed deals, so the full cost shock feeds through only gradually as fixes expire. The transmission to prices is slower than in markets with variable-rate norms.

Supply remains tight (Figure 2 shows completions still below target), limiting the price fall. A large stock-flow imbalance can sustain prices despite weak demand.

Renters bear much of the cost: landlords pass through higher finance costs via rents, worsening affordability for the 19% of households who rent privately (Figure 4).

High rates may reduce new-build activity because development finance is more expensive, worsening the supply problem and preventing the expected price correction.

Regional effects will vary: London and the South East (with the highest prices, Figure 7) may see the largest falls; lower-priced regions like the North East may see little change.

Existing owners may face negative equity if prices fall sharply, but only those with high LTV ratios.

Overall: mortgage rate rises clearly dampen the housing market in the short run, but the effect on prices is gradual because of fixed-rate insulation and limited supply. Rents are likely to rise, worsening affordability for renters even as owners benefit from modest price falls. Allow any other valid points.

1	5	Using the data, discuss whether falling home-ownership rates among younger households (Figure 3) are likely to widen UK regional inequalities.		[10]
Band	AO2 (3 marks)		AO3 (3 marks)	AO4 (4 marks)
3	3 marks Excellent application Figures 3, 6 and 7 used together on both sides of the argument.		3 marks Excellent analysis Well-developed chains explaining the link to regional inequality.	3-4 marks Excellent evaluation Well-developed counter-arguments and a well-reasoned overall judgement.
2	2 marks Good application Data used on one side of the argument.		2 marks Good analysis Developed chains of reasoning.	2 marks Good evaluation Developed counter-arguments.
1	1 mark Limited application Use of data is superficial.		1 mark Limited analysis Chains of reasoning under-developed.	1 mark Limited evaluation Counter-arguments present but under-developed.
0	0 marks No valid application.		0 marks No valid analysis.	0 marks No valid evaluation.

Indicative content

AO2

Figure 3 shows ownership among 25-34s falling from 67% (1991) to 39% (2023) – a dramatic shift.

Figure 7 shows London prices (£525k) more than three times the North East (£160k).

Figure 6 shows regional dwellings per 1,000 people vary from 379 in London to 477 in Scotland.

Widens inequality (AO3)

Young buyers priced out of expensive regions (London, South East) need to either accept long-term renting or move to cheaper regions. Those staying rent, building no housing equity.

Housing equity is the largest component of household wealth. Younger generations locked out of ownership accumulate less lifetime wealth, widening the intergenerational divide – and because wealth correlates with region, regional inequality widens.

Renters pay landlords who are disproportionately located in or connected to already-wealthy areas, concentrating wealth further.

High London rents consume a large share of young workers' income, reducing their ability to save for deposits – a self-reinforcing cycle trapping them in the most expensive region.

Those who do move to cheaper regions may find fewer high-productivity jobs, accepting lower wages and dampening their long-term earnings growth.

Limits / may narrow inequality (AO4)

Falling ownership rates are a national phenomenon (Figure 3 shows it in every age group except 65+), not specifically a regional one. Regional inequality may remain unchanged.

If buyers move from London to the North to afford homes, this redistributes demand and could narrow regional price gaps over time (Figure 7).

Regional investment (Levelling-Up Fund, Investment Zones, Freeports) is directed to lower-income regions, partly offsetting housing-based inequality.

Remote working reduces the wage premium of London-based employment; younger workers can earn London wages while owning a home in a lower-cost region.

Many other factors drive regional inequality: productivity differences, infrastructure investment, education levels, industry mix. Home ownership is only one dimension.

Social housing provision varies by region; where it is more generous, falling ownership matters less for wellbeing.

Overall judgement: falling youth ownership interacts with existing regional price gaps to widen lifetime wealth inequality, especially between those who can afford high-priced southern regions and those who cannot. However, it is one channel among many – broader regional policy, productivity and infrastructure matter more. Allow any other valid points.

Question 2

2	1	Using the information provided on the UK grocery market, outline the characteristics of an oligopolistic industry.	[5]
Band	AO1	AO2	
3		3 marks Excellent application Strong use of the case to illustrate multiple features of oligopoly.	
2	2 marks Good knowledge Comprehensive understanding of the characteristics of oligopoly.	2 marks Good application Good use of the case to illustrate one feature well.	
1	1 mark Limited knowledge Understanding is superficial, incomplete or contains inaccuracies.	1 mark Limited application References to the case are superficial.	
0	0 marks No relevant knowledge shown.	0 marks No valid application.	

Indicative content

AO1 / AO2

A few large firms dominate the market: Tesco, Sainsbury's, Asda and Morrisons (the Big Four) account for around 65% of sales. Figures 1 shows the top six firms (Big Four plus Aldi and Lidl) hold around 83%.

High concentration ratio: four-firm concentration is around 65%.

Significant barriers to entry: economies of scale, access to prime retail sites, established supply chains, loyalty-card data and capital requirements.

Product differentiation through branding, store format, loyalty schemes and own-brand ranges (Clubcard Prices, Nectar Prices, Aldi Price Match).

Interdependence of firms: price-match pledges and matching promotions show clear mutual awareness.

Non-price competition: advertising, loyalty schemes, store innovation, convenience formats, online delivery.

Price rigidity / kinked demand curve: prices tend to be sticky; the rise of Aldi/Lidl triggered the unusual period of price competition.

Ability to earn abnormal profits long-run: the largest firms have consistently reported strong margins.

2	2	Using Figure 2, calculate the marginal revenue (MR) and marginal cost (MC) for each of the output levels (lasagne/week) from 0 to 80,000. Record the answers in your pink answer booklet. Using your answers explain at what level of output FreshMart Ltd will, in theory, maximise profits.		[7]
Band	AO1	AO2	AO3	
3		3 marks Excellent application Comprehensive display of all MC and MR data.	3 marks Excellent analysis Well-developed chain of reasoning explaining the profit-maximising output.	
2		2 marks Good application Strong use of data with either MC or MR correctly calculated.	2 marks Good analysis Developed chain of reasoning showing how profit maximisation is determined.	
1	1 mark Knowledge Knowledge of the profit-maximisation condition is shown.	1 mark Limited application Use of data is limited with significant inaccuracies.	1 mark Limited analysis Chain of reasoning is unconvincing or lacking in clarity.	
0	0 marks No knowledge shown.	0 marks No valid application.	0 marks No valid analysis.	

Indicative content

AO1

Profits are maximised where $MC = MR$ (or, with discrete data, at the highest output at which $MR \geq MC$).

AO2

Price (£)	Qty (000s)	TR (£000s)	MR (£000s per 000 units)	TC (£000s)	MC (£000s per 000 units)
£6.00	0	0	–	20	–
£5.50	10	55	5.5	38	1.8
£5.00	20	100	4.5	50	1.2
£4.50	30	135	3.5	66	1.6
£4.00	40	160	2.5	86	2.0
£3.50	50	175	1.5	112	2.6
£3.00	60	180	0.5	146	3.4
£2.50	70	175	-0.5	190	4.4
£2.00	80	160	-1.5	248	5.8

Credit working:

For MR and MC both correctly calculated: AO2: 3

For MR and MC correctly calculated with minor errors: AO2: 2

For either MR or MC correctly calculated: AO2: 1

AO3

Profits are maximised at an output of 40,000 lasagnes per week (price £4.00) where MR (2.5) exceeds MC (2.0). At 50,000 units, MC (2.6) exceeds MR (1.5), so producing the extra 10,000 units would reduce profit.

Candidates may verify using total profit: $TR - TC = £160k - £86k = £74k$ at $Q = 40$, compared with £63k at $Q = 50$ and £69k at $Q = 30$.

Allow OFR.

2	3	Using a costs and revenue diagram, evaluate the effects on a supermarket's abnormal profits of the expansion of Aldi and Lidl.			[10]
Band	AO1 (3 marks)		AO2 (2 marks)	AO3 (2 marks)	AO4 (3 marks)
3	3 marks Excellent knowledge Accurate diagram showing original monopoly/oligopoly profit rectangle and the leftward shift of AR and MR following new entry.				3 marks Excellent evaluation Impact on abnormal profits fully discussed with a well-reasoned overall judgement.
2	2 marks Good knowledge Diagram with minor errors.		2 marks Good application Case used well (Aldi/Lidl share, price-match response).	2 marks Good analysis Chain of reasoning showing how shifts in AR/MR change profit.	2 marks Good evaluation Developed counter-arguments.
1	1 mark Limited knowledge Diagram with significant errors.		1 mark Limited application Case used weakly.	1 mark Limited analysis Chain of reasoning less well-developed.	1 mark Limited evaluation Counter-arguments present but undeveloped.
0	0 marks No knowledge.		0 marks No valid application.	0 marks No valid analysis.	0 marks No valid evaluation.

Indicative content

AO1

Initial diagram: supermarket operating at $MC = MR$ with AR above AC at profit-max output; shaded rectangle shows abnormal profit. Aldi/Lidl entry shifts AR (and MR) leftwards – the Big Four lose customers to the discounters. AC may rise marginally if retained customers demand more promotions/loyalty rewards. New equilibrium at lower Q with reduced or zero abnormal profit rectangle.

AO2

Aldi has expanded from 3% of the market (2010) to 10.4% (2023); Lidl from around 2% to 7.9% – together 18.3%, largely taken from the Big Four. Aldi Price Match, Tesco Clubcard Prices and Sainsbury's Nectar Prices illustrate the competitive response.

AO3

Entry by discounters increases the number of firms in the market and makes demand more price-elastic. The Big Four's AR (and MR) shifts leftwards.

Supermarkets respond with price-match pledges, narrowing their mark-up over costs and reducing the rectangle between AR and AC at the profit-max output.

Some fixed costs (marketing, loyalty schemes) rise, further reducing abnormal profit.

Abnormal profit falls; in the limit, with free entry and perfectly contestable discount alternatives, profits approach normal.

AO4

The Big Four are differentiated from Aldi/Lidl (wider range, fresh and premium lines, online delivery). This preserves some price-setting power for branded and premium segments, limiting the leftward AR shift.

Investment in automation, private-label expansion and supply-chain efficiency has lowered MC and AC, partially offsetting the profit squeeze.

Aldi/Lidl are not universal substitutes: rural areas and many town centres lack a discounter; local market power survives.

Big Four can use loyalty-card data for price discrimination, capturing additional consumer surplus from members – defending abnormal profits.

Cyclical factors matter: during the 2022-23 cost-of-living shock some Big Four firms reported higher margins in selected categories.

Overall: abnormal profits have fallen meaningfully since 2010 as Aldi/Lidl gained share, but the Big Four retain some abnormal profit through differentiation, cost-cutting, data and scale. Allow any other valid points.

2	4	Evaluate the view that loyalty-pricing schemes such as Clubcard Prices and Nectar Prices are harmful to consumers in the UK grocery market.		[7]
Band	AO1	AO3	AO4	
3			3 marks Excellent evaluation Strong evaluation with a clear overall judgement.	
2	2 marks Good knowledge Clear understanding of loyalty pricing and consumer welfare.	2 marks Good analysis Clear chain of reasoning on consumer harm.	2 marks Good evaluation Developed counter-arguments on consumer benefits.	
1	1 mark Limited knowledge Partial understanding.	1 mark Limited analysis Chain of reasoning lacks clarity.	1 mark Limited evaluation Counter-arguments present but undeveloped.	
0	0 marks No valid understanding.	0 marks No valid analysis.	0 marks No valid evaluation.	

Indicative content

AO1

Loyalty pricing is a form of price discrimination in which the same good is offered at different prices to different customers (members vs non-members). The CMA is investigating whether these practices harm consumers.

Consumer harm (AO3)

Two-tier pricing extracts more consumer surplus: non-members pay effectively inflated prices, so the reference price against which "discount" is advertised may be misleading.

Schemes create switching costs: a shopper's loyalty data, points balance, and tailored offers are lost if they switch, reducing effective competition.

Loyalty data allows supermarkets to identify price-sensitive customers and target them selectively, rather than compete broadly on price.

Non-member prices may be raised relative to underlying cost, so the headline "saving" does not represent a real price cut – the CMA's investigation centres on this concern.

Complexity of promotions exploits bounded rationality: shoppers struggle to compare prices across stores when two tiers of pricing exist.

Counter-arguments (AO4)

Members genuinely pay lower prices – by a meaningful margin. For many households this is a welfare gain even if non-members lose out.

Loyalty schemes are free to join and widely available; the "penalty" for non-membership is avoidable.

The data collected enables supermarkets to reduce waste, forecast demand and tailor ranges – productive efficiency gains that can lower prices overall.

Competition between schemes (Clubcard Prices, Nectar Prices, Aldi Price Match) drives benefits for consumers and limits each scheme's market power.

The CMA retains the power to intervene if investigations find harm; the regulatory backstop limits the scope for exploitation.

Overall: loyalty pricing has mixed effects. Most active shoppers benefit; non-members and the bounded-rational face a real cost. Net welfare likely positive if the scheme rewards a majority of customers, though regulation may be needed to ensure reference prices are genuine. Allow any other valid points.

2	5	With reference to the data, discuss the extent to which the UK grocery market leads to a reduction of economic welfare.			[11]
Band	AO1 (2 marks)	AO2 (2 marks)	AO3 (3 marks)	AO4 (4 marks)	
3			3 marks Excellent analysis Well-developed explanation of welfare reduction.	3-4 marks Excellent evaluation Very well-developed counter-arguments on consumer benefits and efficiency gains; well-reasoned overall judgement.	
2	2 marks Good knowledge Clear understanding of economic welfare.	2 marks Good application Well contextualised use of the case on both sides.	2 marks Good analysis Developed explanation of welfare effects.	2 marks Good evaluation Developed counter-arguments.	
1	1 mark Limited knowledge Some knowledge of welfare.	1 mark Limited application Limited use of the case.	1 mark Limited analysis Partial analysis.	1 mark Limited evaluation Counter-arguments undeveloped.	
0	0 No knowledge.	0 No valid application.	0 No valid analysis.	0 No valid evaluation.	

Indicative content

AO1

Economic welfare is the sum of consumer and producer surplus, adjusted for externalities. It includes allocative and productive efficiency and dynamic (innovation) effects.

AO2

Big Four concentration around 65% (Figure 1); Aldi/Lidl combined 18.3%; CMA investigations into loyalty pricing and supplier relations in 2023-24; supermarket profit margins at the peak of the 2022 cost-of-living crisis attracted political scrutiny.

Harm to welfare (AO3)

Oligopolistic concentration allows firms to set prices above marginal cost, generating allocative inefficiency and a deadweight loss.

Loyalty pricing extracts additional consumer surplus from non-members (CMA investigation).

Market power over suppliers – especially small farmers – can push farm-gate prices below cost, reducing producer welfare and long-run supply resilience.

Barriers to entry (scale, prime sites, loyalty data) restrict new competition.

Dominance of large stores may contribute to decline of independent retailers and weaker high-street competition.

Benefits / limits to harm (AO4)

Competition from Aldi and Lidl has delivered substantial price cuts across the sector – UK grocery prices rose less than most EU countries during the 2022-23 shock.

Economies of scale deliver genuine productive efficiency: UK grocery prices as a share of disposable income are historically low.

Non-price competition has widened consumer choice dramatically: range of own-brand tiers, online delivery, convenience formats, product innovation.

CMA intervention and the threat of it constrains exploitative behaviour.

Loyalty schemes deliver real savings for the majority of shoppers.

Consumer surplus: despite the concentration, UK grocery prices have fallen in real terms over the long run, suggesting substantial consumer benefits.

Overall judgement: the market is concentrated and exhibits some classic oligopoly welfare losses (deadweight loss, supplier squeeze), but the combined effect of discounter entry, scale economies and regulatory oversight means the balance of evidence suggests the market delivers net welfare gains to consumers while imposing costs on suppliers. Allow any other valid points.
